Answers to problem set #1

Supervised Learning: Regression and SVM

Data Mining, Spring 2018

(1) 在多元线性回归模型中:

Hypothesis: $h_{\theta}(x) = \theta^T x = \theta_0 x_0 + \theta_1 x_1 + \theta_2 x_2 + \dots + \theta_n x_n$

Parameters: $\theta_0, \theta_1, \dots, \theta_n$

Cost function:

$$J(\theta_0, \theta_1, \dots, \theta_n) = \frac{1}{2m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)})^2$$

利用梯度下降法求解参数的迭代过程如下:

Repeat
$$\begin{cases} \theta_j := \theta_j - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)} \\ \text{(simultaneously update } \theta_j \text{ for } j = 0, \dots, n) \end{cases}$$

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

$$\theta_1 := \theta_1 - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_1^{(i)}$$

$$\theta_2 := \theta_2 - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_2^{(i)}$$

$$\dots$$

初始化:
$$\theta^0 = (0.00, 0.00, 0.00, 0.00, 0.00)$$
T

将学习率设为1,迭代一次之后:

$$\theta^1 = (93.00, 8376.00, 6864.60, 8059.80, 8501.80)^{\mathsf{T}}$$

(2) 不能。因为

$$J(\theta^0) = 4328.50, J(\theta^1) = 3743077544562.61, J(\theta^0) < J(\theta^1).$$

(3) 经一次迭代后计算
$$\Delta J = J(\theta^1) - J(\theta^0)$$

α	ΔJ
0.1	-37407867726
0.01	-371787909.6
0.001	-3488802.333
0.0001	-11980.34696
1.00E-05	2170.964167
1.00E-06	250. 7864054

因此取 $\alpha = 0.00001$ 可使损失函数经一次迭代下降最快。

(4) 利用标准方程求解参数,公式为:

$$\Theta = (X^T X)^{-1} X^T y$$

% linear regression (normal equation)

% Input: X, the feature matrix (m by (n+1))

% y, the dependent variables

% Output: theta, the parameters

function theta = linear_regression_NE(X,y)

theta = inv(X'*X)*X'*y;

end

求得:

$$\theta = (-19.50, 1.69, 0.38, -0.31, -0.44)^{\mathsf{T}}$$

 $m_{predict} = \theta^{\mathsf{T}} x = 89.51.$

(5) 引入正则化项之后,参数求解标准方程为:

$$\theta = [X^TX + \lambda \begin{bmatrix} 0 & & & & \\ & 1 & & & \\ & & 1 & & \\ & & & \ddots & \\ & & & \ddots & \\ & & & & 1 \end{bmatrix}]^{-1}X^TY$$

$$\lambda = 1, \theta = (-19.99, 1.47, 0.07, -0.23, -0.06)^{\mathsf{T}}$$

 $m_{predict} = \theta^{\mathsf{T}} x = 88.95.$

(对预测结果简单分析, 言之成理即可)。

Logistic Regression

(1)

$$\alpha = 1, \theta = (-2.67, 2.22, 1.06, -1.77, 2.24)^{\mathsf{T}}$$

% Call the library function glmfit
[theta,dev] = glmfit(X,y,'binomial','link','logit');

若调用 Matlab 库函数 glmfit 可得

$$\theta = (-2.67, 2.22, 1.06, -1.77, 2.24)^{\mathsf{T}}$$

对影响子宫内膜癌发病的最直接的因素应为"雌激素药使用"及"非雌激素药使用", 因为通过逻辑回归模型求得的权重参数中这两项的值较大(其他答案言之成理即可)。

logistic regression GD_N.m.

% logistic regression (gradient decent-- normalization)

% Input: X, the feature matrix
% y, the depend variable

% alpha, the learning rate

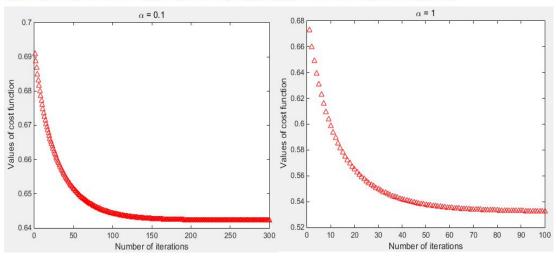

% Iter, the number of iterations

% lambda, the regulaization parameter

% Output: theta, the parameters

% J, values of cost function

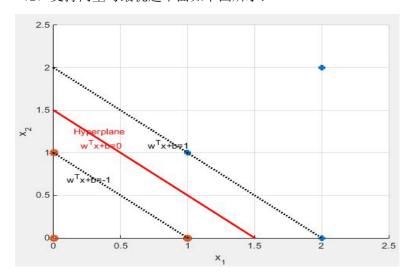

function [theta, J] = logistic_regression_GD_N (X, y, alpha, Iter, lambda)

 $\alpha = \mathbf{1}, \lambda = \mathbf{1}, \theta = (-1.00, 1.08, 0.51, -0.74, 0.81)^{\mathsf{T}}$

3 SVM

(1) 支持向量与最优超平面如下图所示:

其中支持向量为:

$$(1,1)^{\mathsf{T}}, (2,0)^{\mathsf{T}}, (1,0)^{\mathsf{T}}, (0,1)^{\mathsf{T}}$$

由于支持向量满足:

$$\begin{cases} \omega^{\mathsf{T}} x^{(i)} + b = +1, y^{(i)} = +1 \\ \omega^{\mathsf{T}} x^{(i)} + b = -1, y^{(i)} = -1 \end{cases}$$

将坐标点代入可得:

$$\omega = (2, 2)^{\mathsf{T}}, b = -3$$

因此相应的超平面方程为:

$$2x_1 + 2x_2 - 3 = 0$$

由于新增的样本点能被正确分类且远离最优超平面,支持向量不发生变化,用 SVM 训练出 来的分类模型不受影响;而逻辑回归模型的训练则要考虑所有训练样本点,因此新增训练样 本点会影响逻辑回归(其他答案言之成理即可)。

(3)

由(1)可知支持向量为:

$$(1,1)^{\mathsf{T}}, (2,0)^{\mathsf{T}}, (1,0)^{\mathsf{T}}, (0,1)^{\mathsf{T}}$$

两个异类支持向量到最优超平面(决策边界) 的距离之和即为"间隔"(margin):

$$\gamma = \frac{2}{\|\omega\|} = \frac{\sqrt{2}}{2}$$

(4)

对拉格朗日函数求偏导后可得:

$$\omega = \sum_{i=1}^{m} \alpha_i y^{(i)} x^{(i)}$$
$$0 = \sum_{i=1}^{m} \alpha_i y^{(i)}$$

利用互补松弛性质有:

$$lpha_i \geq 0$$
 $lpha_i(y^{(i)}(\omega^\intercal x^{(i)} + b) - 1) = 0$ $\left\{egin{array}{l} lpha_i > 0, x^{(i)} ext{ is a support vector} \ & lpha_i = 0, ext{ otherwise} \end{array}
ight.$

代入支持向量坐标可得:

$$\omega = (\alpha_1 + 2\alpha_3 - \alpha_5, \alpha_1 - \alpha_6)^{\mathsf{T}}$$

求解方程组:

$$\begin{cases} \alpha_1 + \alpha_3 - \alpha_5 - \alpha_6 = 0 \\ 2\alpha_1 + 2\alpha_3 - \alpha_5 - \alpha_6 + b = 1 \\ 2\alpha_1 + 4\alpha_3 - 2\alpha_5 + b = 1 \\ \alpha_1 + 2\alpha_3 - \alpha_5 + b = -1 \\ \alpha_1 - \alpha_6 + b = -1 \end{cases}$$

可得:

可得:
$$\left\{egin{array}{l} lpha_1=3 \ lpha_3=1 \ lpha_5=3 \ lpha_6=1 \ b=-3 \ , \ lpha_2=lpha_4=0 \ \end{array}
ight.$$
 超平面方程为: $\left\{egin{array}{l} 2x_1+2x_2-3=0 \ \end{array}
ight.$

$$2x_1 + 2x_2 - 3 = 0$$
 _{与(1) 中的结论一致。}
